12.1 INTRODUCTION

Hungarian labour market processes were dominated by the economic transition for most part of the 1990s, which involved rapid restructuring and the establishment of adequate institutions to assist the unemployed and respond to other newly emerging needs. This chapter briefly reviews this first stage of institution building before moving on to examine the hypotheses of triple integration, as outlined in the introductory chapter of this volume. Sections follow the same outline as in other country chapters. The results are mixed. We find some indication of the unemployment benefit system moving towards integration in all three dimensions, being strongest in the homogenization of insured benefit and unemployment assistance. In terms of risk re-categorization and the administrative merger of unemployment and social benefits, changes so far appear to have affected goal setting and rhetoric and not much of that has trickled down to the daily practice in local job centres.

12.2 ECONOMIC AND POLICY CONTEXT

12.2.1 The transitional recession

In Hungary, labour market processes had been dominated by the transition from planned to market economy throughout the early 1990s. Political changes in Central and East European countries were followed by dramatic changes in their economies over the early 1990s.

Output fell by 15–25 per cent and there were large shifts in the ownership structure, in the sectoral composition of GDP, and in firm-size distribution. In the gloomiest three years between 1990 and 1993, the cumulative fall in real GDP amounted to 18 per cent (EBRD, 2000: 4).

As some early commentators and the retrospective analyses of microdata have convincingly shown, this was due to the loss of export markets (an aggregate demand shock), followed by disruptions in supply caused by shifts in relative costs and relative demand in response to price liberalization and the removal of subsidies (Blanchard, 1998; Blanchard et al., 1995; Carlin and Landesmann, 1997; Gemula, 1998; Kornai, 1993). In this sense the recession was far more Schumpeterian than Keynesian, and the only effect of macroeconomic policy was to hasten or delay the fall in output and the start of recovery.

In Hungary, the variation in output decline across sectors was rather large and the correlation between relative sector price and output change was high already in 1990, which may indicate an earlier start in restructuring than in other Central and Eastern European countries. The shift was, in rough terms, away from industry and especially heavy industry and towards services. Between 1990 and 1994, the share of industry in total employment fell from 36 to 33 per cent, and services grew from 54 to 58 per cent (Ehrlich et al., 1994). Restructuring also entailed a change of ownership structure. The share of the private sector in producing the GDP as well as in total employment grew at a modest pace during the 1980s, and quickly gathered speed in the first years of the transition. Foreign direct investment was large and accounted for most of this growth from the second half of the 1990s.

Prior to 1989, labour force participation and employment were rather high in Hungary. Female participation was close to 75 per cent and male participation exceeded 80 per cent of the population aged 15–54/59 in 1985. During the transition, unemployment shot up in 1991, peaked in 1993, from when on was very slowly decreasing, while employment dropped from over 71 per cent in 1990 to below 55 per cent by 1993 and continued to decline until 1997 (see Figure 12.1; see also Statistical Annex, Table A.4).

The overall decline in economic activity had a strong impact on certain groups of workers, such as low-skilled workers employed in manufacturing and traditional industries, women, the elderly, the Roma, and young labor market entrants. At the time of the mass layoffs, the low qualified were most at risk of losing their job. In 1992, almost half the ILO-defined unemployed only had primary qualifications, and about one-third of them had lower secondary education. Those closer to retirement age constituted most of the long-term unemployed: their chances of re-employment were very small (Micklewright and Nagy, 1998).

The contraction of demand discussed above naturally led to cuts in employment. The subsequent rise in unemployment could have been temporary, lasting until aggregate demand picked up again. However, with considerable restructuring also taking place, structural unemployment emerged as well. Much of the

---

1 We would like to thank the editors, Pieter vanhuysse and participants of the Recwowe working group, for their helpful comments on the earlier version of this chapter.

2 A Schumpeterian explanation of the recession would stress the importance of structural changes (shifting relative costs and relative demand) and view it as a mix of creation and destruction, while a Keynesian explanation would put the emphasis on falling aggregate demand.

3 Reforms in the early 1980s introduced enterprise contract work associations allowing private economic activity outside the planning mechanism. For more details, see Marer (1986: 251–2) or Kornai (1992: 435–44).
reapportionment of the labour force took place through differential increases in rates of unemployment across sectors, while few new jobs were created (Jackman and Pauna, 1997).

12.2.2 The policy response: reducing labour supply

The adjustment of labour supply to the decline in labour demand followed two channels. Besides the rise in unemployment, which was especially sharp for men, labour force participation fell significantly during the 1990s, especially among women (see Statistical Annex, Table A.7). Government-supported pension policies intended to mitigate the effects of declining labour demand appear to account for most of the decrease in participation. Most people leaving the labour market became eligible to some social provision, such as old-age pension, disability pension, or maternity allowance. By 1995, the share of benefit recipients among the working-age population reached 31 per cent (see Table 12.1).

The use of pension schemes for the reduction of open unemployment started in the mid-1980s, when the mild reforms of the planned economy threatened to increase open unemployment. The government decided to tackle this on several fronts: offering state subsidies on early pension schemes and introducing unemployment insurance (see Section 12.3). Coming into office in 1990, the new democratic government continued and expanded this practice, fearing that the transitional recession would lead to unmanageable levels of unemployment and along with it misery and social unrest (Vanhuysse, 2004).

In order of importance there were four main early-pension programmes: a disability pension, a disability benefit, an early retirement benefit, and a pre-pension. In 1990, these four schemes accounted for 51 per cent of all entries into pensions, while the share of old-age pensions was 40 per cent. By 1992, the share of early-pension schemes increased to 65 per cent, and that of old-age pensions dropped to 26 per cent (see also Figure 12.2). The share of these four schemes slightly declined after 1997, when the pre-pension was abolished and eventually dropped to pre-transition levels by around 2005.

Disability pensions had been available since before the Second World War, while disability benefits in its current form was introduced in 1983. Their eligibility rules remained unchanged during the transition, but the evaluation of claims was rather generous until 1998, when the government finally decided to tighten both the rules and the practice of evaluation committees.

An early retirement pension was introduced in 1988 and extended in 1991. It was available for persons no more than five years below retirement age, with at least thirty years of service time for men and twenty-five years for women (Scharle, 2002). Until reaching the retirement age, the state financed Employment Fund covered up to 50 per cent of pension expenditure, while the employer covered the rest. This subsidy was only available if the firm was shutting down, was making a loss, or carried out mass lay-offs. It was typically used by firms undergoing privatization (Szeman, 1994). Finally, between 1991 and 1997, the

Note: UA (unemployment assistance) includes career starters allowance (radnádott és díjak), and two types of unemployment assistance (izlevélőpénz / tokajegy, rendezett azonosítás alapján), as reported by local councils. Pensions include disability pensions. UI (unemployment insurance) includes insurance-type unemployment benefits (áramlás).

Source: Authors' calculations based on data from the National Statistical Office, the National Employment Office, and the Pension Fund.

---

4 Compulsory funded old-age and disability pension insurance was introduced in 1928 and was replaced by a pay-as-you-go system in 1951, which was gradually extended to cover the total population (including agricultural workers) by 1975.

5 Various benefits (labelled disability benefits in Table 12.3) are paid to claimants not satisfying either the service years or the loss of work capacity condition of the disability pension. The benefit is flat rate if service years are insufficient and wage related if the claimant has sufficient work history but only between 40–67 per cent loss in their work capacity.

6 Initial rules required thirty-five years of service for men, and stricter rules applied for the state-funded part.
pre-pension was available to long-term unemployed people with less than three years to reach retirement age, and having the required service time.\footnote{Excluding disability benefits, the level of all three pension schemes was calculated according to the general rules of old-age pensions, making them much more generous than unemployment transfers. Also, early retirees enjoyed an advantage over others in their age cohort as the years they still had to go until retirement age were ignored in the calculation of their pensions. This was partially eliminated in 1998, when the pre-pension scheme was replaced by a flat-rate pre-retirement unemployment benefit. This benefit was set at 80 per cent of the minimum pension and was conditional on cooperating with the local job centre. It was available to those who had exhausted their eligibility to all other types of unemployment benefit and had only five years or less to reach retirement age (Scharle, 2002). This benefit was eliminated in 2005.}

At a much smaller scale, parental leave was also extended to keep mothers at home and out of the workforce. In 1990, parental leave was available until the 3rd birthday of the child and was conditional on prior employment. It had two phases: an earnings-related allowance in the first two years, and a flat-rate benefit in the third. An extended paid leave was introduced in 1993 for mothers with three or more children, paying a flat-rate benefit until the 8th birthday of the youngest child. Initially, both flat-rate benefits were conditional on prior employment, but were made universal in 1999. Bánlová and Köllö (2008) show that parental leave benefits increasingly became an alternative to social assistance for uneducated young women with little or no employment history.

To summarize, both early pensions and parental leave benefits seem to have served as functional equivalents to unemployment benefits during the transition years. From the perspective of the triple integration framework (see introductory Chapter 1), this may be interpreted as an attempt to narrow down the risk category of unemployment as much as possible – almost exclusively to the able-bodied, prime-age male breadwinner.

Allison and Ringold (1996) report a similar preference for soft measures to cut the workforce in other Central European countries. During the early 1990s, the number of persons on disability pension increased significantly in Slovakia, Poland, and the Czech Republic (see Chapter 13) and old-age pension receipts also showed a marked rise in Slovakia and Poland. In Hungary, there seems to have been a wide political consensus about the aim to build a market economy at a minimum social cost in terms of job loss, rise in inequality, and social tensions (Vanhuysse, 2004). This translated into opening access to all types of provision that facilitated exits from the labour market, ignoring long-term costs.

Though this policy may be rightly questioned in view of the long-term consequences for the balance of the pension fund, there was some justification for it. The transition entailed considerable technological change and it could be argued that this made much of the human capital of older workers obsolete and their retraining did not seem viable given that labour demand was expected to be declining further.\footnote{There was an interlude in 1986, when the earnings-related benefit was abolished, but the prior employment condition of the general flat-rate benefit was lifted as part of an austerity package. The extended paid leave for mothers of three children was left unchanged until 1999, and the earnings-related benefit was reintroduced in 2000 (Bánlová and Köllö, 2008).} However, Balla et al. (2008) show that the preference for benefits over wage subsidies and active labour market measures to facilitate the re-employment of low-productivity workers was an important factor contributing to the persistence of high unemployment. The political gain, however, was clearly positive. As Vanhuysse (2006) argued, early pension policies successfully divided and pacified the large group of workers threatened by unemployment, thereby preventing any serious opposition to emerge against the transition into a fully functioning market economy.

The prevailing growth-oriented mindset of socialist central planners may have also played a role. Successive governments have focused their efforts and attention primarily on macroeconomic growth incentives and regarded employment as a
residual issue in the sense that the level of employment depends on the level of output and hence on growth. While the institutional foundations of competition in the goods market (such as price liberalization, protection of private property, or a public agency to monitor free competition) were laid with much care during the early 1990s, the role of labour market institutions, social policy, and active labour market programmes had been neglected. As we show in Section 12.4, this would only change towards the year 2000, when politicians began to notice that employment had grown at a much slower pace than GDP.

12.2.3 Re-establishing public administration

Since unemployment was virtually non-existent in the socialist era, in the early years of the transition employment policy was dominated by building new institutions to provide unemployment protection. This coincided with a decentralization of government functions in 1990, mostly in response to the political demands of increasing self-governance and to prevent the resurgence of the old regime, which resulted in small and weak local municipalities. While the employment service remained under the control of central government, the management of schools, local infrastructure, and social assistance were devolved to local councils.

Institutional reforms of the central public administration focused on strengthening the executive power of the government (against parliament) and within that the prime minister (Brusis, 2006; Goetz and Wollmann, 2001). This has improved the efficiency of executing government decisions, but not the quality of those decisions. Despite early legislative efforts and some degree of professionalization in key policy areas, successive governments have so far failed to establish a non-partisan professional civil service (Meyer-Sahling, 2009). Coordination across related policy areas, such as social policy and employment policy, has been weak, and clear goal setting, impact evaluation, and adjustment of policies are often missing (OECD, 2007b; Verheijen, 2006).

12.2.4 Changes since the 1990s

The transitional recession and a brief episode of an austerity package in 1996 were followed by steady and relatively high growth in output, but very little increase in employment after 1999 (see Figure 12.1; also Statistical Annex, Table A.4). Before the global crisis in late 2008, the employment rate stood at 57 per cent (age 15–64), which was seven points below the EU average and lowest among the former socialist new member states. As Table 12.2 indicates, over a quarter of the working-age population lived on some kind of social benefit; the majority of recipients were inactive and most of them absent from the labour market for extended periods or permanently.

Note: UA, unemployment assistance; PLB, parental leave benefits (grzg, gyes, and gyet).

The above simple facts suggest that the initial choice of a policy mix dominated by passive (rather than active) labour market measures has proved difficult to reverse, and has become a hindrance to growth. Welfare payments, in combination with the wider system of redistribution, contribute greatly to the persistence of a low equilibrium characterized by low employment and a high burden of taxes and contributions. High tax rates curb economic performance and thus impede economic growth. Long-term unemployment or inactivity among the working-age population in turn leads to long-term poverty, the propagation of poverty from generation to generation, and social exclusion (World Bank, 2001.) And thus the vicious circle closes, in as much as these social disadvantages generate the need for further welfare spending.

The above described 'welfare trap' is especially deep for the less educated who make up over 20 per cent of the population aged 25–64. Less than half of them are in employment, a fifth receives some form of pension-like support, and a tenth is unemployed (see Table 12.3).

---

10 Notably those affected by EU accession or other international commitments, such as fiscal policy (Goetz and Wollmann, 2001). Even in these areas, Meyer-Sahling (2009) recorded a large gap between civil servants' attitudes and personnel practices (examined in the framework of the European Principles of Administration).

11 Vanhuyse (2006) argues that this is partly due to a feedback mechanism whereby the initial expansion of the group of early pensioners makes it politically costly to cut spending on pensions.
12.3 UNEMPLOYMENT PROTECTION IN 1990 AND IN 2010

In the socialist regime, social provisions were supplied primarily through in-kind benefits, price subsidies, full employment, and a compressed wage distribution that was to a large extent controlled by the state. Some social assistance was available to the needy but was meant primarily for the elderly, as working-age adults were expected to be earning their keep through work.12 There was no provision specifically designed for unemployment or in-work poverty; as such problems were considered to be treated at the root, by full employment and decent wages.

The need for introducing such provisions was first recognized in the mid-1980s, when the government decided to increase the autonomy of state-owned firms in managing production and allowed the establishment of small private firms. It was understood that these measures would allow market forces to start operating and this would inevitably lead to some open unemployment. An unemployment insurance (UI) benefit scheme was introduced in 1986. In this scheme, the firm paid the benefit for the first few months, then the central government, and finally the local municipality.

This scheme, however, was never used by a large number of workers, as it was replaced by another in 1989, well before unemployment increased considerably. The new scheme was also based on the insurance principle (contributory record required), but benefits were paid out of the central budget (i.e. there was no dedicated contribution to UI until 1991). The benefit rate was proportional to previous earnings and decreased gradually from 70 to 45 per cent during a spell of unemployment (for more detail, see Appendix 12.A, Tables 12.A.3 and 12.A.4). As the final step to complete the establishment of a two-tier benefit system, a means-tested, flat-rate unemployment assistance (UA) was introduced in 1992 for claimants who had exhausted eligibility for the insurance benefit (Nagy, 2002). Initially, UI was paid for a maximum of two years, while UA was open-ended until 1995, when it was limited to two years. UA was granted to claimants who exhausted UI if their per capita family income was below 80 per cent of the minimum pension; the benefit rate was set equal to this threshold.

Both UT and UA were regulated by the central government and, as of 1991, financed by compulsory contributions from employers and employees to a separate fund which was managed by the government (Keune, 2002). The public employment service (PES) was set up in 1986, but at the time it was primarily intended to facilitate job exchange, since unemployment was well below 1 per cent. The PES network was subsequently strengthened considerably, when registered unemployment grew from below one to over 10 per cent within two years after 1991.

</table>

Other welfare programmes for the working-age population, such as disability pensions, maternity leave, or parental leave benefits, were less affected by the transition to a market economy, as they had already been important parts of the socialist welfare regime. In 1989, the main welfare programmes were all insurance based, as typical of a Bismarckian system. Universal and means-tested schemes introduced during the past twenty years include the above-mentioned UA and a flat-rate maternity allowance introduced in 1996, which was changed from means-tested to universal in 1999. Lastly, a new insurance-based rehabilitation allowance was introduced in 2008. It is granted to new claimants of the disability pension or disability benefit whose work capacity can be partially or fully rehabilitated. The benefit rate is roughly the same as the disability pension13 and it is granted for the duration of the rehabilitation programme but only up to a maximum of three years. The current welfare regulations are summarized in Table 12.5.

Only the unemployment schemes and the new rehabilitation allowance require registration and cooperation with the PES. As a result, the coverage of registered

Source: Authors’ update of table 1.5 in Czeres-Gergely and Schatte (2008a: 39).

Unemployment has been very low; though the majority of the non-employed, working-age population receives some benefit, only 13–16 per cent are registered with the PES. The large majority of the registered unemployed are receiving some form of benefit or allowance, but many of them – about 40 per cent according to labour force surveys – are not actively looking for work (Fazekas et al., 2008: 198). At the same time, about a third of the genuine jobseekers are not registered with the PES. This suggests that the PES is not very effective at activating the unemployed and that the services they offer (beyond administering benefit claims) are poor, or at least perceived to be of poor quality by jobseekers.

The eligibility conditions of all types of unemployment benefit are relatively undemanding in terms of behavioural requirements (Koıtyánı, 2002; OECD, 2001, 2007a), and their enforcement varies greatly across local job centres (Bödös and Nagy, 2008). For example, individual job-search efforts do not need to be documented, and participants in active labour market policies (ALMPs) are exempt from continuing job search and attending interviews with the PES. Personal attendance at the job centres for verifying unemployed status is usually required every one to three months in Hungary, which is much less frequent than in many other countries (OECD, 2007c).

12.4 ANALYSING MAJOR REFORMS

This section reviews the five major episodes of welfare reform in the past twenty years and their political context, with a focus on the divergence or integration of unemployment benefits (for a summary, see Appendix 12.8).

12.4.1 Transition years (1989–92)

Unemployment insurance was established in anticipation of growing unemployment as a result of structural reforms in the mid-1980s, preceding the collapse of socialism and the planned economy. The first major step in employment policy after 1990 was the adoption of the Act on Job Assistance and Unemployment Benefits in 1991, which established a single-tier unemployment benefit system with additional provisions for older workers. It introduced a two-phase UI scheme, the pre-pension, and assistance for school leavers (the latter was abolished in 1996). As discussed in Section 12.3 above, a second tier was added in 1992. The Act was viewed as a necessity to handle the high levels of unemployment emerging at the beginning of the transition – a challenge that the socialist administration had never experienced and hence was not equipped to face. Due to this consensus, there was no opposition to the reforms proposed and all political parties supported the Act.

12.4.2 Reducing generosity (1991–2000)

Unemployment insurance was adjusted frequently during the first half of 1990s, and most of the reforms were aimed at reducing the generosity of the system. As shown in Tables 12.A.3–12.A.4, the prior employment condition was the only element of the UI scheme that was not tightened during this period. Between 1991 and 2000, the maximum duration was cut from two years to 270 days; the replacement rate from 70 to 65 per cent of gross earnings (with a temporary rise to 75 per cent between 1993 and 1997); the maximum UI benefit from three times to twice the minimum wage (1992); and the benefit floor and ceiling not adjusted for inflation between 1993 and 1996, at a time when price levels rose by around 20 per cent a year (Nagy, 2002). The eligibility conditions of the UI scheme did not change until 2000.

With the increase in long-term unemployment, the share of UA claimants reached 45 per cent of all unemployment benefit recipients and has ranged between 50–60 per cent since then (IE, 2009). At the same time, UI and UA converged in terms of average payments. When the UA scheme was introduced in 1992, on average benefits amounted to less than half the average UI benefit, but reached 64 per cent by 1997. The average UI benefit dropped from 56 to 36 per cent of the average net wage (Nagy, 2002). This was mostly a result of the above-mentioned drop in the real value of the benefit floor and ceiling. Nagy (2002) shows that the benefit amount was determined by the ceiling in 35 per cent of UI benefit claims in 2000, as opposed to 2 per cent in 1992, while the floor was applied in ever fewer cases (7 per cent in 2000 vs 43 per cent in 1992).
The gradual retrenchment in unemployment protection was met with little resistance. Part of the explanation for this may lie in the early divide-and-conquer policies, which provided other, often more generous types of support (early pension, disability pension, maternity leave) to claimants who had a sufficiently long enough employment history, thereby helping to prevent the emergence of discontent among social groups with a significant bargaining power. Trade unions were also too weak to raise their voice. They had been weakened by the dismantling of large state-owned firms and lost their former powers to influence government decisions via the communist party. In the new legislative framework, social partners are solely involved in pre-legislation discussions about unemployment support, rather than implementation or administration (Neumann, 2007).\\n
The deep and abrupt welfare cuts of the so-called Bokros package in 1996–7 were not so easily accepted. For the UI scheme, the replacement rate was reduced from 75 to 65 per cent, its two phases merged into one, and the ceiling was further reduced in real value (there was a small nominal rise, but not enough to make up for the lack of adjustment in the preceding five years). The pre-pension was replaced by the considerably less generous pre-retirement unemployment benefit, the earnings-related paid parental leave was abolished, and the insured flat-rate paid parental leave was replaced by a means-tested assistance (with no prior contribution required). In response, the unions went on strike, the minister for welfare resigned, and MPs of both the ruling coalition and the opposition parties raised their voice against the welfare cuts but the austerity package was nevertheless passed amid the looming financial crisis (Antal, 2000; Kelen, 1996).\\n
12.4.3 The supply incentive experiment (2000–2)\\n
With a conservative coalition (Fidesz – Hungarian Civic Union, joined by the Small-holders Party) coming into power, a comprehensive ‘welfare to work’ reform was adopted in 1999. The government’s programme for 1998–2002 underlined the need to reduce state redistribution and costly means-tested welfare systems, and support self-help (Fidesz, 1998: 5). According to official rhetoric, the programme was justified by the need to support people who are willing to help themselves and the government’s responsibility to safeguard the interests of the tax-paying citizen (Fidesz, 1998: 3; Lakner, 2005). The main goal was to increase incentives for the unemployed to actively seek employment. Measures included the introduction of activation plans, cutting the maximum duration of UI, the merger of UA with the regular social assistance, and doubling the minimum wage in two years.

In 2000, means-tested UA was merged with the more general social assistance scheme (see footnote 12) and made available regardless of prior work history. The benefit level was cut from 80 to 70 per cent of the minimum old-age pension. The new scheme maintained the character of a UA support in that eligibility was conditional on cooperation with the job centre or the local welfare agency. In addition, the work test was considerably strengthened in an effort to focus more on activation and workfare (Frey, 2001). Most notably, eligibility for the new scheme was dependent on claimants engaging in thirty days of public works (prior to accessing benefit) which was paid at a rate no lower than the minimum wage.\\n
This development made UI and UA more similar in terms of job-search criteria, but more distinct in all other respects and particularly in terms of generosity. Between 1997 and 2006, the average amount of the UI and UA schemes diverged, mostly because the UA had not been fully adjusted to inflation and wage increases. While UI transfers were typically around 40 per cent of the average net wage, the average UA dropped from 26 to 16 per cent of the average wage during the period (IE, 2008).\\n
The administration of the new UA was devolved to local governments in 2000, who were reimbursed by the central government for most of their expenditure on UA. The fact that dedicated grants could not be used for other purposes (Semjén, 1996) created a disincentive for the local governments to strictly enforce job-search regulations for UA. In addition, many municipalities (especially in villages) merely paid out benefits, lacking the adequate expertise for the provision of genuine employment-oriented assistance to the long-term unemployed. One year after the introduction of the new work test, half of all municipalities had not organized public works at all, which was mostly due to the lack of administrative and managerial capacity (Fazekas, 2001). On the other hand, larger municipalities benefited from the reform as it provided a new source of funding for public works and extended the eligible types of work to any activity that ‘served the public interest’.

As a whole, the ‘welfare-to-work’ reform resulted in a divergence between UI on the one hand and UA on the other in terms of eligibility and in administering support. There was little or no integration of risk categories either, since the reform focused rather narrowly on the registered unemployed. Other than implementing the gradual increase of the standard retirement age as set out in the pension reform of 1997 (drafted by the previous government), there was no attempt to extend labour market integration efforts to a wider group of benefit claimants.

Another element of the ‘welfare-to-work’ reform was a rise of the minimum wage in 2001–2. The prime minister promoted this as an incentive for people to seek employment via increasing the gap between wages and welfare (Kertesi and Köllö, 2003). In political debates over the plan, politicians also referred to the
moral obligation to grant decent wages for all workers, the need to approximate local wages to Western levels, and to suppress informal employment (Cserpes and Papp, 2008; Orbán, 2001). The government tended to downplay the potential labour demand effect noted by economists and also the European Commission (JAP, 2001), but introduced some measures to compensate employers.18 Besides the genuine belief that it would raise employment, the minimum wage hikes may have been intended to appeal to middle-class voters and perhaps also to increase public revenues (Kaufman, 2007).

Reactions to the workplace measures were rather mixed. Employers, experts, and opposition parties stressed the potentially negative effects of the increase in minimum wage on labour demand. The Socialist Party accused the government that the minimum wage rise was intended mainly to boost government revenues (Kovács, 2001). The largest trade union federation of socialist orientation (MSZOSZ) worried about potentially adverse employment effects (Cserpes and Papp, 2008; Kertesi and Kolló, 2003),19 while public employees protested because the rise removed much of the wage advantage of skilled workers and professionals in public health care and education. The new UA conditions also attracted fierce criticism by the socialist and liberal opposition, stating that the proposal was based on prejudice against the poor (and the Roma), ineffective, and would thus hurt the long-term unemployed especially in underdeveloped regions where there were few opportunities to work (Parliament, 1999). However, public opinion strongly approved of compulsory public works for UA recipients though not of the benefit cuts. The support for the new work test was so strong that the overall acceptance of the reform was positive (Kolló, 2002).20

Subsequent impact analyses of the reform identified few favourable results. A simulation of budgetary impacts showed that the minimum wage increases were unlikely to reduce unregistered employment and their net effect on the budget was expected to be negative. The employment effect was proved definitively negative by detailed empirical analyses (Kertesi and Kolló, 2003).21 Galasi and Nagy (2002) also showed that the tightening of UA did not significantly increase re-employment probabilities, while it substantially reduced the income of the long-term unemployed.

18 These included a 4 per cent cut in social security contributions (implemented over two years) and a temporary relief fund for low-wage sectors.

19 Unions were also alienated by the tactics of the government in introducing the minimum wage rise. In November 2000, the parliament adopted an amendment to the Labour Code authorizing the government to set the minimum wage where the process of negotiations with the social partners did not yield agreement. Social partners feared that the new rule would weaken the social dialogue in this area. Indeed, the first rise in 2001 was passed by government decision, without the consent of the social partners (Cserpes and Papp, 2008; IAP, 2001).

20 International attitude surveys suggest that – as in most post-socialist countries – disapproval of income inequalities and support for publicly financed welfare provisions is much stronger in Hungary than in the old EU member states (Murthi and Thiongson, 2008). However, most people would prefer to allocate benefits on the basis of merit, rather than needs (TARKI, 2002).

21 For an overview of the impact analyses and the ensuing debate over further increases in the minimum wage, see Benedek et al. (2006).

12.4.4 Combining welfare and activation (2002–8)

After the 2002 elections, the new socialist–liberal government was mainly concerned with correcting relative wages in the public sector (as the wage distribution had been distorted by the minimum wage rise). One of their first measures was a 50 per cent wage rise for persons employed in the public health-care and education sectors, while the minimum wage was only raised by the level of inflation. Besides a minor alteration of the UI scheme in 2003,22 there was no change in the unemployment benefits until late 2005. Learning the lesson of the unsuccessful supply-side measures of the previous government, the Socialist administration re-established the Ministry of Labour and concentrated more on demand-side policies, such as targeted wage subsidies. In 2003 the re-elected coalition – possibly inspired by EU recommendations – redesigned the benefit system with an aim to provide strong incentives for job search, but at the same time adequate levels of income support. UI was renamed as ‘job-search’ provision, and behavioural conditions were further tightened (Frey, 2006: 208). To encourage early exit from benefit receipt, the new UI was made heavily front loaded in 2006 (see Table A.12.4) and a re-employment bonus was introduced.23 The new UI had three phases: a wage-related first phase and a flat-rate second and a third phase with declining rates of support. The maximum duration was reduced by ninety days but the average benefit amount increased considerably in the first phase as both the floor and the ceiling of UI were raised, which compensated for the drop in the replacement rate from 65 to 60 per cent. Opposition parties mainly supported the expansion of ALMPs but challenged the government to make the activation measures more concrete.

In April 2006, the UA became a minimum income scheme, and the benefit amount dependent on equivalent family income (rather than per capita income). As intended, the redesigned allowance was more effective in reducing poverty, and especially child poverty, but also raised concerns about widening the unemployment trap, as there was no phasing out or disregard for those entering a job. It also generated tensions in some municipalities, where officials considered the provision too generous, in some cases based on prejudice against large Roma families. In response, the allowance was capped in December 2006, fixing its maximum level equal to the minimum wage (Firle and Szabó, 2007).

Aided by EU support under the Phare and HRD programmes, the PES was reorganized into a regional system (as opposed to the former network of county headquarters) and gradually started to introduce new, client-oriented services designed to support individual job search. To support job exchange and monitoring, a national information system was established, accessible by all local PES offices, and PES staff received training to implement internal quality assurance and evaluation (Galasi, 2004).

22 To ‘correct the negative effects of the 1999 amendment’, the government reintroduced the second phase of the UI, with special, more favourable conditions for those with less than five years before retirement age (see Tables A.12.3 and A.12.4; also Frey, 2003: 176).

23 Those getting back to work before exhausting benefit would receive 50 per cent of the benefit amount which would have been due for the rest of the benefit duration.
The strengthening of activation has been on the agenda of the PES since the late 1990s and especially since Hungary joined the European Union in 2004. Activation plans as a tool to increase motivation for job-search were introduced in 2003, which had a positive effect on job-search efforts (Galasi and Nagy, 2009). There is some evidence, however, that such activation efforts have mainly affected UI recipients. Bódis and Nagy (2008) find that the drafting and enforcement of activation plans have remained a largely formal exercise, and especially so in the case of UA recipients. In the labour force survey, one in two UA recipients reports to have visited the local job centre within a month, compared to one in four UI recipients. This apparent difference in the implementation of behavioural requirements for the two groups suggests there is no clear tendency towards the administrative integration of unemployment benefits.

Finally, activation was gradually extended to claimants of other working-age support. Wage subsidies and training programmes were gradually extended to cover disabled persons, less-qualified workers, older workers, and mothers re-entering the labour market. The boldest of such measures was the introduction of a rehabilitation allowance in 2008. As already mentioned in Section 12.2, this was granted to new claimants of the disability pension or disability benefit whose work capacity can be partially or fully rehabilitated (as assessed by a committee of health and employment experts). Recipients of the allowance must cooperate with the PES and participate in trainings or other rehabilitation services as required by the PES. The impact of the new measure has been limited so far, partly because the supply of personalized rehabilitation services is scarce and partly because the global crisis has reduced employment prospects.

12.4.5 Responding to the global crisis (2009–10)

The global financial crisis reached Hungary in late 2008. Within a year, unemployment rose from 8 to 10 per cent, and employment (in the population aged 15–64) dropped from 57 to 55 per cent. The government responded by cutting employers’ social security contributions, increasing subsidies for job retention schemes, and further tightening the UA benefit (see below, and for more details Cseres-Gergely and Scharle, 2010). The crisis weakened the Hungarian currency, also because it coincided with political turmoil erupting in early 2009. The political crisis ended with the resignation of the prime minister and the announcement of an austerity package in April 2009, designed to regain foreign investors’ confidence. The package included some long overdue but politically difficult measures, such as abolishing the so-called ‘13th month pension’, raising the retirement age to 65, and reducing the maximum duration of paid parental leave to two years. It also included a general 10 per cent reduction in government staff, which was applied to the PES as well, not considering the obvious increase in the demand for their services.

Changes made to UA were similar to those in 2000, except more severe. Recipients of the old UA were divided into two groups: those considered able to work, and those too frail to do so. For the latter group, the benefit amount remained unchanged and the work test was removed. For the former, the benefit amount was flattened and considerably reduced and the work test extended to ninety days of public works a year, paid at least at a rate equivalent to the minimum wage. Long-term unemployed aged over 55 were automatically put in the ‘frail’ category, thereby narrowing the risk category of the unemployed. The cut in the UA benefit amount widened the gap between UI and UA recipients further, particularly since many of the newly unemployed were better-paid skilled workers laid off from crisis-ahind manufacturing firms. The two groups converged, however, in terms of job-search requirements and also in benefit administration as able-bodied UA recipients are now served by the PES instead of the municipalities. Public works remained a municipal responsibility and available funds were considerably increased.

The austerity measures were clearly a response to the financial crisis and the structural dysfunctions of the Hungarian economy which had caused a slowdown even before the global crisis. The tightening of UA, however, had been on the agenda since its controversial redesign as a minimum income scheme in 2006. In one interpretation, the amendment in 2009 was a political deal with the powerful lobby of mayors (Kis, 2010). In return for their consent to the austerity measures, mayors were allowed to use the UA for regulating the (idle) poor and especially the Roma, and for filling gaps in their budgets via public works funds, which were not closely scrutinized by the central government. The tightening may have also served to appease the growing public discontent over the inefficiency of Roma integration policies (and a gloomy economic prospect) and to prevent the further growth of support for the far-right.

12.5 Conclusions

In terms of the triple integration hypothesis (see Chapter 1), we may summarize the changes in the unemployment benefit system as follows. There was some homogenization of unemployment benefit support caused mainly by the gradual cuts in the generosity of the UI scheme. However, the reform of late 2005 was rather mixed in this respect since it reduced entitlement while increased the replacement rate in the UI scheme, which may be interpreted as moving back towards the traditional separation between insurance-based and means-tested support. This is also underlined by the fact that neither scheme has become

24 By law, both UI and UA recipients should visit the local job centre at least once in three months. The National Employment Office recommends that UI recipients are called more frequently: at least once a month. The LFS data suggest that in practice, the average frequency of visits is two months for UI and four months for UA recipients (calculation by Ágota Scharle based on the second quarter of the Hungarian Labour Force Survey of 2005).

25 The 3,176 mayors who are elected directly in each village, town, and city may hold a seat in parliament as well, and many of them do, which clearly increases the power of their lobby.

26 Established in 2003, Jobbik ('The Movement for a Better Hungary') burst onto the political scene by winning three of the twenty-two Hungarian seats at the EU elections in 2009.
Regulating the risk of unemployment

dominant in terms of coverage. At the same time, the generosity and entitlement to the means-tested scheme were increased, which brought the average level of payments closer to the insured benefit. The latest reforms of 2008–9 reversed this trend, so the gap between UI and UA widened again.

A need for risk re-categorization, that is, making parallel programmes for working-age claimants more like unemployment support, or making labour market exit routes less attractive, has been propagated by international experts since the mid-1990s, but Hungarian governments have been very slow or inconsistent in taking such advice. Early measures merely aimed to reduce the generosity of working-age benefits in 1996–7, while easing access (to early pension, parental leave) at the same time. This was later reversed by curbing access to pre-pension and disability schemes in 1998. Efforts of broadening unemployment as a risk category also included parental leave recipients who became eligible (but not required) to participate in some active labour market programmes but the extension of a work test requirement to the incapacity benefit was only introduced in 2008. Registration at the local job centre has been kept as a condition of claiming UA, though it is often merely an administrative formality. The latest rearrangement of the UA, however, has again narrowed the focus of the PES by removing older workers from the unemployment register.

The idea of an administrative merger of distinct support systems for working-age benefit recipients has been widely discussed in the past few years but most of these plans are still waiting to be implemented. The new rehabilitation scheme with a work test introduced in 2008 was a first major step in this direction since it moved the main responsibility of dealing with this client group from the health and pension insurance agencies to the public employment service. The ministries of welfare and labour were merged in 2006, and the national headquarters of the PES have assumed some new roles related to social provisions. However, the local level no merging of welfare and PES functions has taken place so far. Indeed, there are signs of diminished integration as indicated by the strengthened responsibility of local governments in managing public works programmes for UA recipients.

In summary, the suggestion of integrating working-age benefits or their administration has been a frequent element in policy debates, but has not materialized yet in the actual design and implementation of employment policy. Rather than responding to structural changes or distortions in the labour market, policymaking has been largely dictated by the politically determined cycle of overexpending and fiscal squeeze, and more specific short-term political aims, such as the recent attempt to appease public discontent by regulating the 'idle poor'. Most labour market reforms would necessitate complex deals and potential gains can often be reaped only by the next government. This reduces governments’ intrinsic motivation to initiate reforms, while civil society, the media, and fiscal watchdogs are still too weak to hold them accountable. Even when a hard-fought political decision is made, implementation may fail on the restricted or uneven ability of public administration to adequately design a new policy and ensure its proper implementation.

Note: *The increase in non-recipiency is partly explained by the phasing out of the school-leavers allowance in 1996, and partly by the tightening of UI and UA rules. In 2007, the share of those aged below 30 was 40 per cent among non-recipients, and 24 per cent among the other registered unemployed.

### 13 The Czech Republic: activation, diversification, and marginalization

**Tomáš Sirovátka and Ondřej Hora**

#### 13.1 INTRODUCTION

This chapter analyses the development of the social protection of the unemployed in the Czech Republic (and the former Czechoslovakia) since the early 1990s. From the perspective of the framework for analysis that informs this volume, the Czech case presents a number of specificities. With the exception of the closure of some exit routes for elderly workers, there is little evidence of the blurring of the boundaries between the risk of unemployment and other forms of working-age benefit dependency, or of any convergence in eligibility and entitlement rules between unemployment protection and other schemes for non-working populations. Nor is there any trend to benefit homogenization; on the contrary, in the Czech case there is evidence of growing diversification in benefit rights, in several respects: between unemployment insurance (UI) and social assistance (SA) concerning replacement rates and entitlement conditions, and in the approach to different subcategories of the unemployed (e.g. long-term and short-term claimants, the youth). However, a strong trend to activation can be seen in the Czech case, both in schemes for the unemployed and in SA.

In more concrete terms, in the early 1990s the first post-communist Czech governments introduced a two-tiered benefit system, comprising UI and SA. The system was quite encompassing, and though it was not overly generous, it provided an acceptable living standard. Activation elements were originally neglected in both schemes. The UI and SA schemes would later converge, because of rather modest standards in UI and the development of SA into a relatively generous safety net. Since the late 1990s, however, changes in the benefit system have moved in the opposite direction: towards a strengthening of insider–outsider differentiation and the movement of some groups out of the scope of unemployment protection altogether. Over the course of the 2000s strong activation
